Abstract

This work aims to study extraction of essential oil (EO) from peppermint leaves using hydro-distillation methods. The peppermint oil extraction with hydro-distillation method studied the effect of the extraction temperature on the yield of peppermint oil. Besides, it also studied the kinetics during the extraction process. The second-order mechanism was adopted in the model of hydro-distillation to estimate many parameters such as the initial extraction rate, capacity of extraction, the constant rat of extraction at various temperatures and activation energy. The results showed that the extraction process is a spontaneous process, since the Gibbs free energy has a negative value at all studied temperatures. For example the Gibbs free energy at (70, 80, 90, and 100 °C) were (-2.93, -4.75, -5.66) respectively.

Keywords: hydro-distillation, Arrhenius equation, entropy change, enthalpy change, Gibbs free energy, Peppermint leaves

1- Introduction

An EO is a concentrated hydrophobic liquid containing volatile aromatic compounds from plants [1]. Essential oils are also known as ethereal oils or oil fly [2]. EO is generally derived from one or more plant parts, such as flowers, leaves, stems, bark, wood, roots and seeds [3]. EO is a mixture of saturated and unsaturated hydrocarbons, alcohol, aldehydes, esters, ethers, ketones, oxides, phenols and terpenes that may produce characteristics [4]. Essential oils are generally colorless to slightly yellowish and only slightly soluble in water and dissolve fairly well in an organic solvent and mix very well with vegetable oils and fats. Many essential oils have antibacterial, anti-fungal, and antiparasitic properties [5],[6].

One of the most particular source of plant containing EO is peppermint. Peppermint belongs to the family of Lamiaceae [4]. Peppermint oil is derived from the peppermint plant, a cross between water mint and spearmint, which is indigenous to Europe and North America but now grown throughout the world [7]. Peppermint oil has been widely used as flavoring in foods, beverage, as a fragrance in soaps, cosmetics, health and tobacco industries [4,7]. The Food and Drug Administration lists peppermint and peppermint oil as “generally recognized as safe” [8], [9]. Chemically, the major constituents of the peppermint oil include the terpenes, menthol, menthone, isomenthone, methyl acetate, menthofuran and 1, 8-cineol[7,8]. Peppermint can be used in the medicinal preparations as well as a flavoring agent in foods and confectionery [8].

There are several methods can be used for extracting essential oils such as expression and organic solvent distillation processes. However, hydro-distillation is one of the commonly used for several advantages such as simplicity and non-solvent involvement [10],[11],[12]. The purpose of this research is to study the process of oil extraction from peppermint leaves using a hydro-distillation method. In this research, the effect of temperature to the yield of peppermint oil and kinetics during the extraction process based on a second-order extraction model will be studied. Then, studying of the methods for determining the initial extraction rate and the saturated extraction capacity will be conducted. In addition, the energetic aspect of the EO extraction will be studied. The current work presents first tempt to study the parameters of thermodynamic using this type of EO. Then, Arrhenius equation parameters will be estimated at different temperature.

2- Materials and Methods

2.1. Experimental Work

Leaves of the peppermint plants were collected from a local market. The leaves were dried in shade for ten days, and then it was crashed. Twenty gram of peppermint leaves were introduced to Pyrex extraction flask with 400 ml of distilled water. The flask is equipped with electrical stirrer at 100 rpm. A water bath was used to control the extraction temperature. The extraction of peppermint oil was conducted at different temperature (343k, 353k, 363k and 373k).
The process continued until the equilibrium was reached. Then, the peppermint oil was collected and stored at laboratory conditions. Fig. 1 shows a schematic diagram of the experimental setup. The concentration of EO was calculated by multiplying the volume of EO by the density of oil divided by the total volume of solvent.

Fig. 1. Schematic diagram of the hydro-distillation setup: 1; Water bath, 2; thermometer, 3; stirrer, 4; Electric motor and 5; condenser

2.2. Kinetic Model of Peppermint Oil Extraction

The second-order extraction kinetics model, is a commonly used model for the solid-liquid-extraction process, was chosen in the present work.

\[
\frac{dc_t}{dt} = k_e (C_s - C_t)^2
\]

Where: \(k_e\) (Lg\(^{-1}\)m\(^{-3}\)) is rate constant for 2nd-order model, \(C_s\) (L) is the concentration of essential oil at saturation (extraction capacity) and \(C_t\) (L) is the concentration of peppermint oil at any time \(t\) (min). By grouping variables, equation (2) is obtained:

\[
\frac{dc_t}{(C_s - C_t)^2} = k_e dt
\]

The boundary conditions are \(t = 0, C_t = 0\) and \(C_t\) at time \(t\). Integrating the rate equation for a 2nd-order extraction gave equation (3):

\[
C_t = \frac{C_s^2 k_e}{2 \times k_e + C_s k_e}
\]

Rearrange equation (3) to get equation (4):

\[
\frac{1}{C_t} = \frac{1}{k_e C_s^2} + \frac{1}{C_s}
\]

By rearrange equation (4), the rate of extraction (equation 5) can be written as:

\[
C_t = \frac{1}{(2/k_e C_s^2) + (1/C_s) t}
\]

When \(t\) approaches 0 the initial extraction rate, \(h_i\), as \(\frac{1}{C_t}\) can be written as equation (6):

\[
h_i = k_e C_s^2
\]

At any time, the concentration of peppermint oil can be expressed as:

\[
c_t = \frac{1}{(1/k_e C_s^2) + (1/C_s) t}
\]

Equation (3) can be rearranged to be as shown in equation (8):

\[
\frac{1}{C_t} = \frac{1}{h_i} + \frac{1}{C_s}
\]

By plotting experimental values of \(\frac{1}{C_t}\) versus \(t\), the values of the initial extraction rate \(h_i\), the saturation concentration addition to the constant of 2nd-order extraction rate, can be determined using both the slope and intercept.

2.3. Activation energy

Arrhenius equation is given by equation (9), where it can be used for kinetics study.

\[
k_e = A \exp(-E_A/RT)
\]

Where: \(k_e\), the extraction rate constant, \(T\) (K) is the absolute temperature of extraction process, \(R\) (3.814 J mol\(^{-1}\) K\(^{-1}\)) is gas constant, \(A\) (Lg\(^{-1}\)m\(^{-3}\)min\(^{-1}\)) is Arrhenius factor and \(E_A\) (kJ mol\(^{-1}\)) is activation energy of extraction.

Equation (10), a linear relationship between \(k_e\) and \(1/T\) can be obtained from equation (9).

\[
\ln k_e = \ln A + \left(\frac{-E_A}{R}\right) \frac{1}{T}
\]

Where: the Arrhenius equation constants, \(A\) and \(k_e\) are known for the extraction process, while \(E_A\) can be calculated.

2.4. Thermodynamic parameters

Thermodynamic parameters for the extraction of peppermint oil were estimated using Van’t Hoff equation [1]:

\[
\ln K_e = \frac{-\Delta G^0}{R} \frac{1}{T} = \frac{-\Delta H^0}{R} \frac{1}{T} + \frac{\Delta S^0}{R}
\]

\[
\Delta G^0 = \Delta H^0 - T \Delta S^0
\]

Where: \(K_e\) is equilibrium constant, \(T\) (K) is absolute temperature of extraction process, \(R\) is gas constant, \(\Delta G^0\), \(\Delta H^0\), and \(\Delta S^0\) is Gibbs free energy, enthalpy and entropy of extraction. Enthalpy and entropy can be calculated via plotting \(\ln K_e\) vs \(1/T\).
3- Results And Discussions

3.1. Effect of Extraction Temperature

Fig. 2 shows influence of temperature on extraction of peppermint oil. The effect of extraction temperature on the peppermint oil extraction kinetics was studied from 70 to 100 °C. Increasing the temperature of extraction increases peppermint oil yield. For each temperature, the rate of extraction started with sharply increase more than afterwards.

The final concentration of EO was increased when the extraction temperature increased as shown Fig. 2. This is because the higher temperature increases the rate of peppermint extraction (evaporation) and the diffusion of the peppermint oil during the process becomes faster [2],[13],[14],[15],[16],[17]. The different concentrations between the peppermint leaves and water phase represent a driving force for the diffusion of soluble oils according to the fundamentals of mass transfer between the phases (Fick’s law). The mass transfer rate, then, reaches a zero when the equilibrium state is occurred. In fact, the dissolution process and diffusion process are dominated in the extraction of the EO according to the different concentrations between the solid phase and bulk liquid phase [18].

Fig. 2. Influence of temperature on the concentration of peppermint oil

3.2. Kinetics of Peppermint Oil Distillation

Peppermint oil extraction process occurs in two successive stages: (i) dissolution and scrubbing process can be created by the fresh solvent (as driving force); (ii) then external diffusion of peppermint oil into the extract giving a much slower stage. This shows phenomena typical of a 2nd-order kinetic model. The plotting of Cs vs. time explained that phenomena. Fig. 3 shows the results of this analysis.

Fig. 3. Second-order extraction kinetics of EO in hydro distillation method from peppermint leaves at various temperatures

The amount of oil extracted increases rapidly with time at the beginning of the process. It decreases slowly with the time reaching the end of extraction process [10],[13],[19],[20],[21]. Equation (1) can be used to calculate the rate of extraction for the peppermint oil which is contained in the solid parts used.

The value of kr, Cs, and hi, were determined through slope and intercept after linearization step as shown in Table 1.

The initial rate of extraction, hi, increased with extraction temperature. Also, Cs and kr, of 2nd-order kinetic model behaved in the same manner. Moreover, from Fig.4 the capacity of extraction in the high temperature (100 °C) was always superior to that the lower temperature (70 °C). At the high temperature of extraction, the rate was faster than that at low temperature as can be seen in Fig.5 [22],[2].

However, at high temperature, the rat constant of extraction was higher than at low temperature.

The main reason for these results is that the cell penetration and diffusion are better in the high temperature [2].
3.3. Activation energy

The Arrhenius equation (9) obtained by plotting $\ln(k_r)$ versus $1/T$ Fig. 6. The plot of $\ln(k_r)$ vs. the reciprocal of the absolute temperature allows for calculating Arrhenius constant, $A$, and activation energy, $E_A$.

There was a linear relationship between $\ln(k_r)$ and $\frac{1}{T}$ with a determination coefficient of 0.9779. From Fig. 6, the Arrhenius constant, $A$, is $4.9126 \text{ (L/g-min)}$, and the activation energy for extraction, $E_A$, is $55.109 \text{ (kJ/mol)}$, showing that the extraction is an endothermic process.

3.4. Thermodynamic Parameters

Table 2 displays the values of $K_e$, $\Delta H$, $\Delta S$ and $\Delta G$ respectively at different temperature for the peppermint oil extraction process. While the plot of $\ln K_e$ versus the reciprocal of the absolute temperature $1/T$ that used to determine the value of thermodynamic parameters, is shown in Fig. 7.

</tbody>
</table>

The value of $\Delta H$ and $\Delta S$ for the peppermint oil extraction were positive in the ranges of extraction temperature. Thus, this extraction process of the peppermint oil is shown to be both irreversible and endothermic.

The previous studies reported same results for the extraction of sunflowers oil [23], olive oil [15], soybeans oil [24], cottonseeds oil [25] and hempseed oil [26]. The value of $\Delta H$ gave the quantity of energy that the extraction process mixture; i.e., peppermint leave and water, should adsorb so that the peppermint oil extraction process can happen.

From Table 2, $\Delta G$ was negative which shows that the extraction process of peppermint oil is favorable and spontaneous. The spontaneous nature of the extraction of the peppermint oil was favored with increase the extraction temperature.
4- Conclusion

In this study, the kinetics of the EO extraction from peppermint leaves at different temperatures is based on a 2nd-order model. Consequently, it can be concluded that the mechanism of the EO extraction proceeds in two steps: a fast dissolution of peppermint oil followed by slow external diffusion of solute from the plant leaves. Cs, k, and the hi can be predicted with this 2nd-order model as a function of the temperature. In accordance with an endothermic process, the yield of peppermint oil is found to increase with extraction temperature. The value of $\Delta G^\circ$ showed that the extraction process of peppermint oil is irreversible and endothermic process. $\Delta G^\circ$ shows that the extraction process of peppermint oil is favorable and spontaneous.
